Transportation Project Prioritization Study

CMAAG

TRANSPORTATION PROJECT PRIORITIZATION STUDY 2010 **TPPS**

FINAL REPORT | NOVEMBER 2010

PREPARED FOR:

Coachella Valley Association of Governments
73-710 Fred Waring Drive, Suite 200
Palm Desert, California 92260

PREPARED BY:

5095 Murphy Canyon Road | Suite 330
San Diego, California 92123
Phone: (619) 683-2933
Fax: (619) 683-7982

JOB NUMBER:
JA92102

ACKNOWLEDGEMENTS

The Transportation Project Prioritization Study project final report represents the combined efforts of the Project Team and the associated committee members and local agency staff. Through a series of project team and committee meetings, the elements of the final report were refined.

CHAPTER S

EXECUTIVE SUMMARY

BACKGROUND

The Transportation Project Prioritization Study (TPPS) serves as an unbiased, methodological way to provide CVAG direction in determining funding for regional arterials by prioritizing the eligible study segments. This chapter summarizes the scoring results and costs and compares them with results from the 2005 TPPS update.

The Coachella Valley Association of Governments (CVAG) is responsible for the distribution of sales tax (Measure A) Transportation Uniform Mitigation Fees (TUMF) and other funds to be used for transportation related projects in the Coachella Valley area. In order to better determine the prioritized need for arterial road improvement projects, CVAG has developed the TPPS.

The study area includes the incorporated areas of the Coachella Valley as well as a portion of the County of Riverside. The cities include: Cathedral City, Coachella, Desert Hot Springs, Indian Wells, Indio, La Quinta, Palm Desert, Palm Springs, and Rancho Mirage. In all, the study area encompasses approximately 300 miles of roadways including: 293 study segments, 11 intersections, 6 existing interchanges, 10 new interchanges and over 50 bridges.

2005 TPPS

Project Evaluation Criteria

The TPPS compares significant roadway segments for these nine municipalities and the County of Riverside in the Coachella Valley area using distinct evaluation criteria and scores to form a ranking list used in deciding where funding should be directed. The criteria used to analyze the improvement needs are determined by the CVAG Transportation Technical Advisory Sub-Committee (TTAS). The TPPS prioritization is based on four main criteria and five bonus point criteria of roadway characteristics.

Primary Scoring Criteria

Each primary criterion is analyzed and scored between 0 and 5 points resulting in a ranking of road projects in order from the highest to the lowest to provide a technical basis to evaluate the prioritized need for improvements. **Table S-1** summarizes the scoring convention.

Table S-1 | Roadway Segment Scoring Criteria

Points	Roadway Surface Condition	System Continuity	Level of Service	Accident Rate
0	--	Improved to Ultimate	A	0.00
1	Good	Atypical Width / Widening	B	0.01 - 0.90
2	Satisfactory	Add Travel Lanes	C	0.91 - 3.90
3	Fair	New Road or New Interchange	D	3.91 - 6.90
4	Poor	New Bridge or New Low Water Crossing	E	6.91 - 9.90
5	Very Poor - Failing	Missing Link	F	9.90 +

Roadway Surface Conditions

Under a separate pavement management contract with CVAG, the pavement conditions were determined for each study segment. The condition of the road surface is calculated using Pavement Condition Index (PCI) methodology in the MicroPaver Pavement Management System (PMS) software. The PCI is a rating that ranges from 100 for a brand new pavement to 0 for a totally failed pavement.

System Continuity

The System Continuity criterion gives values to segments based upon the ultimate planned improvements and scored by a relative value that the improvement would benefit overall regional circulation. This classifies a segment as requiring additional lanes, widening, a new road, bridges and interchanges and scores them appropriately.

Level of Service

Level of Service (LOS) is defined as a qualitative measure describing operational conditions of traffic. It is a report-card scale used to indicate the quality of traffic flow on roadway segments and at intersections, with the best LOS being "A" (free flow, little congestion) and worst LOS being "F" (forced flow, extreme congestion). For each roadway segment, the level of service is calculated using the segment's volume and theoretical capacity to calculate volume/capacity (V/C) ratios.

Accident Rate

The accident rate was scored for segments and intersections within the study based on the calculated rate from available data. The data used included information for accidents involving injuries, fatalities, and a large proportion of the "property damage only" motor vehicle traffic accidents reported in California. The data used for this project is the most recent 3 years, beginning January 1, 2006 and ending December 31,

2008. Accident rates are calculated using volumes, degree of severity, and segment lengths, except for study intersections which do not require length in their calculation.

Bonus Point Criteria

Segments within the TPPS study can also qualify for extra points based upon characteristics chosen by the CVAG and the TTAS, which add to the total score each segment receives. A total of five bonus points can be earned in this study. These criteria are listed in **Table S-2**.

Table S-2 | Bonus Point Criteria

Points	Bonus Point Criterion
1	Construction Cost for Buildable Project is Less Than \$1,000,000
1/2 to 1	Project Readiness: If R/W Available, Env. Document Approved, Agency Funds Reserved, Plans or Specs Complete
1/2	Segment is a Whitewater River (or Major Tributary) Crossing
1/2	Segment meets criteria as a Backbone Level Project

Construction Cost Less than \$1,000,000

Based on the construction costs developed under a separate effort, all segments associated with projects with a construction cost less than \$1 million will be awarded one bonus point. This does not consider R/W costs or impact costs in the formula to receive this bonus point.

Project Readiness

A project's relative readiness will be based on what stage the proposed projects have progressed, including R/W availability, environmental clearance, completed plan and specifications, and availability of matching city funds. Coordination with the TTAS was performed to determine logical requirements for the criteria. Each segment project that demonstrated one or two of the "project-ready" characteristics is awarded a ½ bonus point. Segments that adequately meet three or four characteristics are given 1 full point.

Whitewater River or Major Tributary Crossings

If the project includes a Whitewater River channel or major tributary defined as a "blue water stream" on a USGS map, it will receive a ½ bonus point toward its project priority score.

Backbone Level Projects

Projects determined as integral to continued and future development of an area and their relative importance in regional circulation will be given a ½ bonus point. These projects are typically large scale and will be approved for eligibility defined by CVAG and the TTAS.

Buildable Projects

After all segments have been analyzed using criteria set forth by CVAG and the TTAS, they can then be merged or divided into logical and feasibly constructible buildable projects. The score for a buildable project is simply the average of the score for each segment that is part of its defined limits.

CONCLUSION

The results of this study will be used by CVAG as an evaluation tool to help define budgeting priority for the improving segments in this study. The higher ranked projects should be considered first for funding opportunities.

Tables S-3 to S-6 list the final rankings for the buildable projects and important scoring information used to create these rankings.

Intersection of Frank Sinatra Drive and Hwy 111

CHAPTER 1

PROJECT STUDY ORGANIZATION

BACKGROUND

The Coachella Valley Association of Governments (CVAG) is responsible for the distribution of sales tax (Measure A), Transportation Uniform Mitigation Fees (TUMF), and other funds to be used for transportation related projects in the Coachella Valley area. In order to better determine the prioritized need for arterial road improvement projects, CVAG has developed the Transportation Project Prioritization Study (TPPS). The TPPS was first completed in 1989 in response to the voter approved Measure A sales tax to help identify and rank the regional roadway infrastructure with the greatest needs for improvements.

2005 TPPS

The TPPS compares significant roadway segments for the nine municipalities and the County of Riverside in the Coachella Valley area using distinct evaluation criteria and scores to form a ranking list used in deciding where funding should be directed. The criteria used to analyze the improvement needs are determined by the CVAG Transportation Technical Advisory Sub-Committee (TTAS) and have been adjusted on subsequent report updates in 1993, 1999, and 2005 to reflect the most recent evaluation methodologies and current priority needs. The TPPS prioritization is based on four main criteria and additional bonus point criteria of

roadway characteristics. Each criterion is analyzed and scored resulting in a ranking of road projects in order from the highest to the lowest to provide a technical basis to evaluate the need for improvements. The TPPS identifies factors that may alter recommended priorities and is part of a continuing monitoring program, which allows for CVAG to address changing conditions over time.

STUDY AREA

The study area includes the incorporated areas of the Coachella Valley as well as a portion of the County of Riverside. The cities include: Cathedral City, Coachella, Desert Hot Springs, Indian Wells, Indio, La Quinta, Palm Desert, Palm Springs, and Rancho Mirage. In all, the study area encompasses approximately 300 miles of roadways including: 291 study segments, 9 intersections, 7 existing interchanges, 10 new interchanges and over 50 bridges.

PROJECT GOALS

Ultimately the TPPS will be one part of the information that helps CVAG to prioritize the future transportation needs and determine where funding is allocated to meet these needs. Although this is a living document that is updated on a periodic basis, this current update will be utilized for the next few years to make decisions on priority project funding. Therefore, this study needs to be very comprehensive and thorough in the evaluations of the study area.

The primary project goals include:

- A review and update of prioritization criteria and analysis methodology
- Comprehensive and unbiased evaluation of all selected roadway segments
- A usable and accessible reporting of the scoring and ranking

STUDY PROCESS OVERVIEW

In order for this study to be effective, a combined effort and coordination with all of the study area agencies is necessary. The TTAS members have been involved by meeting on a regular basis to provide necessary data, review materials and provide input on the evaluation methodologies and preliminary rankings. The overall process to complete this study includes:

- Review the list of qualifying arterials to be studied
- Conduct field work and collect data for TTAS member review
- Create a comprehensive database with all of the information for each study segment
- Review and update methodologies and rankings for each criteria
- Accurately score each segment based on approved criteria
- Create a website access interface to work with local agencies and report preliminary results
- Determine a list of buildable projects
- Estimate improvement costs by segment and buildable project
- Report the final score ranking of all of the roadway segments

STUDY SEGMENT SELECTION

The Coachella Valley study area is a large area with a vast roadway network. This study specifically addresses improvement needs for regionally significant arterial roads. Not all road segments are eligible to be included in the TPPS. Therefore, it must first be determined which road segments meet the specified criteria and then coordinate with local agencies for segments being considered.

In order for a segment to be a part of the TPPS, the roadway must meet at least three (3) of the following five (5) criteria:

- Roadway must connect to, or cross over, Interstate 10 or SR 86S
- Roadway must go through, or border, two or more jurisdictions
- Roadway must be shown in an agency's general plan as a minimum four-lane roadway/street
- Roadway segment volume (measured in current year) must exceed 20,000 ADT both directions
- Roadway must cross the Whitewater River Channel or a major tributary

COMPLETED PROJECTS

Since the last TPPS update was completed in 2005, there have been a number of roadway segments that have either been constructed, are currently under construction, have received funding, or have been determined to be infeasible. These study segments are considered to be "completed" and are therefore not eligible to compete for funding as part of this TPPS update. They are removed from consideration in this study. Projects that have completed design packages (plans, specifications and estimates) are not considered complete and are eligible to compete for funding. All of the completed projects are listed on **Table 1-3**.

FINAL STUDY SEGMENT LIST

After the above criteria are evaluated for each segment a final list of the study segments is developed. It includes all projects still competing from the previous TPPS report as well as any additional eligible road projects requested by the agencies that meet the requirements shown within the previous section. All eligible road projects requested by the participating agencies are then divided into manageable uniform segments to study them more consistently using common segment characteristics. The roads are segmented using the following guidelines:

- A segment should be approximately 1.0 mile in length with logical termini
- Jurisdictional boundaries should be recognized if possible
- Road segments owned and maintained by multiple jurisdictions may serve as a reason to define a segment
- Significant structures, such as bridges crossing over channels, should be considered as separate segments
- Highway interchanges should be considered separate segments
- Arterial street intersections may be studied as individual segments
- Current development should not define segments

The 58 study area roadways were finally divided into 292 manageable roadway “segments” that can be studied and the list is shown on **Table 1-4**. See **Figure 1-1** through **Figure 1-6** for segments.

Monterey Avenue at Interstate 10

Intersection of Frank Sinatra Drive and Hwy 111

CRITERIA AND SCORING

The primary purpose of the TPPS is to evaluate the regionally significant roadway segments in the Coachella Valley area using standard methodologies for impartial reporting of improvement needs and ranking each to determine relative priority for project funding. The way that this evaluation is accomplished is by using four main criteria and five bonus criteria to score and rank each segment to determine the relative priority. For each TPPS criterion, a score between 0 and 5 was assigned to each segment. These scores, along with any bonus points received, are tabulated and ranked from highest to lowest score. The segment receiving the highest score is concluded to have the highest relative priority for the study segments. The following describes each scoring criterion and **Table 1-1** summarizes the scoring convention.

Main Criteria

There are four main scoring criteria for each of the study roadway segments. These main criteria have been developed to provide a comprehensive evaluation of the segments and to score them comparatively. These scoring points carry the greatest weight and generally have the most affect to the overall ranking.

Table 1-1 | Roadway Segment Scoring Criteria

Points	Roadway Surface Condition	System Continuity	Level of Service	Accident Rate
0	--	Improved to Ultimate	A	0.00
1	Good	Atypical Width / Widening	B	0.01 - 0.90
2	Satisfactory	Add Travel Lanes	C	0.91 - 3.90
3	Fair	New Road or New Interchange	D	3.91 - 6.90
4	Poor	New Bridge or New Low Water Crossing	E	6.91 - 9.90
5	Very Poor - Falling	Missing Link	F	9.90 +

Roadway Surface Conditions

Roadway surface condition is one of the criteria used to prioritize projects within the CVAG TPPS study. Under a separate pavement management contract with CVAG, the pavement conditions were determined for each study segment. The condition of the road surface is calculated using Pavement Condition Index (PCI) methodology in the MicroPaver Pavement Management System (PMS) software. The PCI is a rating that ranges from 100 for a brand new pavement to 0 for a totally failed pavement and is an internationally recognized indicator of apparent structural condition and functional condition and is recognized as the most common means to rate and communicate pavement conditions throughout the United States and abroad. Pavement conditions were surveyed for all ten jurisdictions within the study area using video-automated technology in order to score the segments consistently.

System Continuity

The System Continuity criteria gives values to segments based upon the ultimate planned improvements and scored by a relative value that the improvement would benefit overall regional circulation. For example, using this methodology, new roads or bridges planned for the region are given a greater value than those that currently exist and require widening. Each segment's existing roadway width will be compared to the ultimate improved standard based upon its classification in the agency's adopted Master Plan or Circulation Element to determine the level of necessary improvement. More points are awarded for those segments that improve capacity and enhance the regional roadway network the most.

Level of Service

Level of Service (LOS) is defined as a qualitative measure describing operational conditions within a traffic stream taking into consideration such factors as speed, travel time, freedom to maneuver, comfort, convenience, and safety. It is a report-card scale used to indicate the quality of traffic flow on roadway segments and at intersections. The roadway Level of Service ranges from LOS "A" (free flow, little congestion) to LOS "F" (forced flow,

extreme congestion). For each roadway segment, the level of service is reported using the segment's volume and theoretical capacity to calculate volume/capacity (V/C) ratios, which are associated with LOS values used by the Institute of Transportation Engineers (ITE) in their Level of Service methodology. Average Daily Traffic (ADT) volumes are provided by CVAG, and have been supplemented where necessary with new traffic counts.

MicroPaver is utilized for pavement condition database

Accident Rate

The accident rate scoring criteria includes scoring the road segments and intersections within the study based upon the relative rate of accidents. The traffic accident criteria ranks each individual road segment in the TPPS based on the overall accident rate following the procedural guidelines recommended by the Transportation and Traffic Engineering Handbook (Second Edition) and Caltrans accident data on California State Highways. The accident data comes from the Statewide Integrated Traffic Records System (SWITRS), which is an accident database maintained by the California Highway Patrol (CHP) that serves as a hub of local (city or county) and state police agency information. SWITRS includes information for accidents involving injuries, fatalities, and a large proportion of the “property damage only” motor vehicle traffic accidents reported in California. The data used for this project is the most recent 3 years, beginning January 1, 2006 and ending December 31, 2008. The raw accident data is reduced into usable data and sorted into the proper studied segments. Agencies were also able to provide alternative data if available. Accident rates are calculated using volumes, degree of severity, and segment lengths, except for study intersections which do not require length in their calculation.

Statewide fatalities per 100 million VMT

Bonus Point Criteria

Segments within the TPPS study can also qualify for extra points based upon characteristics chosen by the CVAG and the TTAS, which add to the total score each segment receives. A total of five bonus points can be earned in this study. These criteria are listed in **Table 1-2**. More detail on qualifications and results for bonus points are shown in Chapter 6.

Construction Cost Less than \$1,000,000

Based on the construction costs developed under a separate effort, all segments associated with projects with a construction cost less than \$1 million will be awarded one bonus point.

This does not consider R/W costs or impact costs in the formula to receive this bonus point.

Project Readiness

A project's relative readiness will be based on what stage the proposed projects have progressed, including R/W availability, environmental clearance, completed plan and specifications, and availability of matching city funds. Coordination with the TTAS was performed to determine logical requirements for the criteria. Each segment project that demonstrated one or two of the "project-ready" characteristics is awarded a ½ bonus point. Segments that adequately meet three or four characteristics are given 1 full point.

Whitewater River or Major Tributary Crossings

If the project includes a Whitewater River channel or major tributary defined as a "blue water stream" on a USGS map, it will receive a ½ bonus point toward its project priority score.

Backbone Level Projects

Projects determined as integral to continued and future development of an area and their relative importance in regional circulation will be given a ½ bonus point. These projects are typically large scale and will be approved for eligibility defined by CVAG and the TTAS.

Table 1-2 | Bonus Point Criterion

Points	Bonus Point Criterion
1	Construction Cost for Buildable Project is Less Than \$1,000,000
1/2 to 1	Project Readiness: If R/W Available, Env. Document Approved, Agency Funds Reserved, Plans or Specs Complete
1/2	Segment is a Whitewater River (or Major Tributary) Crossing
1/2	Segment meets criteria as a Backbone Level Project

REPORT ORGANIZATION

The report is organized in chapters dedicated to the analysis of each criterion for all roadway study segments. While this chapter discusses the overall background and organization of the study, Chapter 2 through Chapter 5 analyze and score each segment using the four main criteria while Chapter 6 discusses all of the bonus point criteria and scoring. Chapter 7 then summarizes the results and totals the scores.

CHAPTER 2

ROADWAY SURFACE CONDITION CRITERIA

BACKGROUND

Roadway surface condition is one of the criteria used to prioritize projects within the CVAG TPPS study. The pavement surface condition survey was performed using the Pavement Condition Index (PCI) methodology and procedures for distress identification used in the MicroPAVER Pavement Management System (PMS). Pavement conditions were surveyed for all ten jurisdictions within the study area in order to score the segments consistently.

ROADWAY SURFACE CRITERIA

Pavement surface conditions were measured using PCI methodology, based upon criteria used in the MicroPAVER system. The PCI methodology is a visual pavement distress survey procedure, which identifies pavement distresses, severity and extents, and uses standard deduct curves to calculate a PCI. The PCI is a rating that ranges from 100 for a brand new pavement to 0 for a totally failed pavement. The PCI is an internationally recognized indicator of apparent structural condition and functional condition and is recognized as the most common means to rate and communicate pavement conditions throughout the United States and abroad.

Using PCI methodology, roadway pavements are divided and subdivided into groups that have similar characteristics or exhibit a common function, such as surface type, pavement rank, cross section and traffic.

Pavements that have a common usage, such as an entire street define a segment (MicroPAVER name it Branch instead of Segment). The street pavements are identified by their segment and section numbers. Segments are pavement sections within a segment that have the same surface, consistent construction history, cross-section, traffic and use. Sections are further subdivided into sample units which are small pavement areas, typically 100 feet in length by the street width, and these are visually inspected in detail. The inspection data used to calculate the PCI for each section includes distress type, its extent, and severity.

PAVEMENT CONDITON FIELD SURVEY

In April and May of 2010, an automated pavement distress survey to assess the pavement surface condition was performed for the majority of the primary roadway sections within the study. The automated survey was supplemented with a visual survey of the remaining segments, using standard sampling methodology to estimate a segment's pavement condition index. Pavement condition assessment is one of the primary decision variables in any pavement management program, or in this case, for project planning and cost estimation. Pavement condition results help identify the functional condition of the pavement surface as well as the underlying pavement structure.

Using this automated process, all data was collected continuously and recorded in 100-foot intervals on a block to block basis. The Laser RST double pass tested each arterial roadway driving in the outer most lanes. The van collects detailed data that is strung together at a later time to match the agencies existing or requested segmentation.

For this survey, IMS used a Laser Road Surface Tester (RST) enhanced with digital imagery and GPS capabilities. The RST, with its 11 laser sensors is capable of collecting a full array of pavement condition data complete with high accuracy GPS coordinates and multiple view digital images for both rigid and flexible pavements (in real time), as it traverses the roadway. An integrated Digital Condition Rating Subsystem supplements the RST data for additional distress data elements, quality assurance and inventory information. Specialized data processing, using GIS as its backbone, allows the pavement data to be quickly checked for completeness and quality. As a standard of practice, IMS utilized the protocols defined by the U.S. Army Corps of Engineers commonly referred to as ASTM D6433-09. The information collected by IMS was then ported into a Micropaver GIS network and assessed.

Field Road Surface Tester Equipment

DATA INPUT AND PCI ANALYSIS

The MicroPAVER pavement management system computer program was used to store and analyze data for CVAG, as all city members of CVAG have agreed to use the Micropaver software for pavement condition data purposes. All the segment and section data were inputted into the program creating a “CVAG” database.

The automated data from the survey was collected on 100% of the driven lane of a road segment. We then reduce that down to 100ft sample lengths for upload into MicroPAVER. The remaining surveys were completed using a typical sampling procedure that estimates the condition of a roadway based upon a representative sample of the road and extrapolated to resemble the entire segment.

Following the completion of the pavement surveys, data processing, and loading of the data to MicroPAVER, a comprehensive report and analysis was developed. This phase of the project is dedicated to analyzing the data collected with the intent of developing a report containing all findings and recommendations.

MicroPAVER program was then used to calculate PCI for each section. The PCI is a composite pavement condition rating ranging from 100 for a pavement in perfect condition to 0 for a totally failed pavement. The weighted average PCI for each segment consisting of several sections was then calculated.

The PCI procedure identifies 19 distresses for flexible pavements (AC surfaces) and 19 distresses for rigid pavements (PCC surfaces). Each distress has three severity levels: low, medium, and high. The PAVER Field Manuals have definitions and guidelines for distress identification, how to measure quantities and how to rate the severity (low, medium, or high) for each distress. In this way the subjectivity of the inspector is minimized.

The screenshot shows the MicroPAVER 6.1.2 software interface. The main window is titled 'Summary data at time of inspection'. It contains several input fields and buttons for data entry and calculation. Below the input fields, there is a section for 'Distress Type' with a grid of checkboxes for 19 different distress types. A 'Distress Severity' section allows selecting Low, Medium, or High severity. A 'Distress Quantity' field shows a value of 736.00. At the bottom, there is a table listing the entered distresses with columns for Distress, Description, Severity, Quantity, Units, and Comments.

Distress	Description	Severity	Quantity	Units	Comments
1	ALLIGATOR CR	L	736	SqFt	
12	POLISHED AG	M	1,582	SqFt	
11	PATCH/UTILITY	L	4,324	SqFt	
10	LONGITUDINAL/L		40	ft	
15	RUTTING	L	630	SqFt	

Examples of MicroPaver

RANKING SEGMENTS

Scores calculated through the MicroPaver program are defined by default program classifications. Segments were classified as "Failed", "Serious", "Very Poor", "Poor", "Fair", "Satisfactory", or "Good".

All conditions that were classified as "Very Poor" or worse were given the maximum of 5 points. Segments with "Poor" conditions or better were given 1 to 4 points. Segments that did not exist were classified as "Does Not Exist" and were given a score of 5 points. See **Table 2-1** for scoring criteria and points.

ROADWAY SURFACE CONDITION CRITERIA RESULTS

See **Table 2-2** for scoring results by segment. Scores from the 2005 study were also included on this table for comparison.

Table 2-1 | Roadway Surface Condition Classifications and Point Conversion

<i>Condition Rating Number</i>	<i>Roadway Surface Cond. Classification</i>	<i>Roadway Surface Cond. Criteria Points</i>
86 +	Good	1
71 - 85	Satisfactory	2
56 - 70	Fair	3
41 - 55	Poor	4
26 - 40	Very Poor	5
11 - 25	Serious	5
0 - 10	Failed	5
N/A	Does Not Exist	5

CHAPTER 3

SYSTEM CONTINUITY

BACKGROUND

The System Continuity criterion gives values to study area roadway segments based upon the ultimate planned improvements. More points are awarded for those segments that improve capacity and enhance the regional roadway network the most. For example, new roads or bridges planned for the region are given a greater value than those that currently exist and only require widening or added lanes. Each segment's existing number of lanes and roadway width will be compared to the ultimate improved standard based upon its classification in the local agency's adopted Master Plan or Circulation Element to determine the level of necessary improvement.

SYSTEM CONTINUITY METHODOLOGY

Each roadway segment was scored based upon the ultimate planned improvement it needed and scored by a relative value associated with how the level of improvement would benefit regional circulation. Using this methodology, new facilities that complete the regional arterial network are valued higher than improvements to existing facilities. The process used to determine improvement classifications for each road segment is described below.

Example: Existing roadway cross-section

Example: Proposed roadway cross-section

Table 3-1 | Typical Roadway Classification List

DETERMINING IMPROVEMENT STANDARD

Each segment's existing number of lanes and roadway widths were measured and compared to the ultimate improved roadway standard. This ultimate improvement is based upon the roadway's classification in the agency's adopted Master Plan or Circulation Element. The minimum number of lanes a segment provided within its described limits was used as the existing number of lanes in this study. Therefore, "pinch points" or "bottlenecks" become the critical portion of the segment considered in the analysis. The roadway widths were measured from curb to curb, or edge of traveled way to edge of traveled way. By comparing the existing and planned values, a determination was made as to the level of necessary improvement.

When segments were within the jurisdiction of two or more agencies, the planned classification that required the most improvements was considered in the analysis. **Table 3-1** lists the typical roadway classifications for each agency that were used for this study.

Example: City circulation element

CLASSIFICATION DEFINITIONS

The System Continuity improvement of a roadway was defined by one of six different categories:

1. Fully Improved –

Fully Improved roadway segments are existing segments that do not require any additional lanes or other road widening and are considered fully improved.

2. Atypical Width / Widen –

Segments are classified as potentially needing widening if the width requirements of the improvement standard were greater than the existing curb-to-curb width, although the segment may have the correct number of lanes. Widening for roads, bridges or interchanges were considered as equal types of improvements

3. Add Travel Lanes –

When an existing paved road, bridge or interchange has less than the ultimate planned number of lanes, it is classified as needing to “Add Travel Lanes”.

4. New Roads or New Interchanges –

Planned roads, unpaved roads, and roads planned for extension are categorized as “new roads”. New interchanges with Interstate 10 or State Route 86S are within this classification as well. Existing interchanges qualify for widening or added lane improvements.

5. New Bridge or Low Water Crossing –

When a roadway needs a new bridge or low water crossing to separate it from a railway or drainage flow, it is considered to be in this category.

6. Missing Link –

A new road or new bridge segment is classified as a missing link if a continuing arterial maintains the arterial on both ends of the segment’s limits

Completed: WSH1 – Washington Street Bridge between Avenues 50 and 52

Monterey Interchange at I-10

Typical roadway widening

CRITERIA AND SCORING

Scores were assigned to the segments based upon the following scheme shown in **Table 3-2**. New roads, bridges or interchanges planned for the region are given a greater value than those that exist and require adding lanes or correcting an atypical cross-section. Segments classified as missing links are given the highest score. Fully improved segments were not given any points.

Table 3-2 | System Continuity Classification Scoring Criteria

Points	System Continuity Classification
0	Improved to Ultimate
1	Atypical Width / Widen
2	Add Travel Lanes
3	New Road / New Interchange
4	New Bridge or Low Water Crossing
5	Missing Link

SYSTEM CONTINUITY CRITERIA RESULTS

The planned roadway segment classifications are shown in **Table 3-3**. The required improvements are shown in **Table 3-4** and the final scoring for System Continuity are shown on **Table 3-5**. See **Figures 3-1** through **Figure 3-6** graphically show the roadway segments and the scoring results.

CHAPTER 4

LEVEL OF SERVICE CRITERIA

BACKGROUND

This chapter of the study analyzes the roadway segment operating conditions in terms of "Level of Service" (LOS), which is a common measure of traffic congestion of roadways. The level of service criteria compares the existing traffic volumes to the theoretical capacity of each project segment, and a LOS is calculated. The LOS criterion is used in this study to measure the need for improvements to the study roadways based on the level of traffic congestion that is experienced.

DEFINITION OF LEVEL OF SERVICE

The concept of LOS is defined in the 2000 Highway Capacity Manual (HCM) (Transportation Research Board Special Report 209) as a qualitative measure describing operational conditions within a traffic stream, and the motorist's and/or passengers' perception of operations. A LOS definition generally describes these conditions in terms of such factors as speed, travel time, freedom to maneuver, comfort, convenience, and safety.

Level of service is a report-card scale used to indicate the quality of traffic flow on roadway segments and at intersections. Level of service (LOS) ranges from LOS "A" (free flow, little congestion) to LOS "F" (forced flow, extreme congestion).

Levels of service for roadway segments can generally be categorized as follows:

- LOS "A": Free-flow, or near free-flow conditions.
- LOS "B": Free to stable flow, light to moderate volumes.
- LOS "C": Stable flow with moderate volumes; freedom to maneuver noticeably restricted.
- LOS "D": Approaches unstable flow with heavy volumes; very limited freedom to maneuver.
- LOS "E": Extremely unstable flow; maneuverability and psychological comfort extremely poor.
- LOS "F": Extremely congested; forced or breakdown flow.

Examples of different levels of service

Example of traffic levels on Washington Street in the midday peak hour

LEVEL OF SERVICE METHODOLOGY

The generally accepted method for determining the LOS of a particular roadway segment is by comparing segment traffic volumes and theoretical roadway capacity. This methodology is consistent with previous TPPS updates. The peak hour volume and capacity data is used to calculate volume to capacity (V/C) ratios for each study segment by dividing the directional peak hour volumes by the hourly traffic capacity. The resulting ratio is then translated to an appropriate level of service using standard values shown in **Table 4-1**. Intersections are studied using the Intersection Capacity Utilization (ICU) method which uses critical flow ratios similar to V/C.

Although theoretical capacity can not exceed a V/C ratio greater than 1.00, there are some roadways and intersections that may exceed this level due to other roadway factors that allow for greater traffic flows than what a standard roadway is expected to carry. These segments are considered to be over capacity and are given a LOS F.

Table 4-1 | Volume /Capacity Ratio and Level of Service and Point Conversion

LOS Criteria Points	Level of Service	Volume / Capacity Ratio	ICU %
0	A	0.00 - 0.60	0.0% - 55.0%
1	B	0.61 - 0.70	55.1% - 64.0%
2	C	0.71 - 0.80	64.1% - 73.0%
3	D	0.81 - 0.90	73.1% - 82.0%
4	E	0.91 - 1.00	82.1% - 91.0%
5	F	1.01 +	91.1% +

DATA COLLECTION

To get accurate characteristics of the study area, each segment within the TPPS was surveyed for physical characteristics in January 2010. Among the items observed were the number of lanes in each direction, type of roadway control, and the type of median configuration that exists within each segment.

For analysis purposes each segment was separated into three possible types of roadway control:

- Uncontrolled (Intersecting streets stop or yield to traffic along this segment)
- Stop-Controlled (Segment stops at an intersecting street; stop sign controlled)
- Signal-Controlled (Traffic signals control traffic flow along segment)

Avenue 52 at Grapefruit Boulevard
Separate intersection turn movements were taken at the
9 study intersections

Many segments have traffic controls at their limits, but may not have controlled intersections in between. After a certain distance, a traffic control will no longer influence the capacity of a segment. For segments that were two miles in length or more, the control type was considered to be “uncontrolled” if no controls existed within the limits of the segment, excluding the segment terminus points.

The median characteristics were determined from the data collection and the types of medians for all segments were categorized into five possible types:

- Double-yellow stripes only (DY Only)
- Left turn lanes at intersections only (Int Left Turns)
- Left turn lanes at intersections and all major driveways (All Left Turns)
- Two-way left turn lanes (TWLTL)
- Raised medians with curbs (Raised)

Segments that are striped with a double-yellow line to divide traffic are classified as “DY Only”. If the segment has left turn lanes, it was given one of the other four classifications, as appropriate. For one-way streets, the median type was designated as “Raised”.

Occasionally, where the study segment might have characteristics that vary greatly over the length of the segment, the study segment was divided into smaller sections to keep the physical features along the specific segment more consistent. The minimum number of lanes was used if the number of lanes varied within a segment, to represent the limited capacity of the roadway without the complete number of lanes. Similarly, when roadway controls varied along the study segment, the control type associated with the lesser capacity was used (e.g. stop-controlled has a lesser capacity than a signal-controlled). If median types varied within the segment, the most prominent feature seen along a segment was used. Table 4-2 summarizes the roadway elements for all segments within the study at the end of this chapter.

Peak Hour Volumes

Traffic volumes for the TPPS were taken using certain standard guidelines common to most traffic engineering studies. Because traffic volumes can vary greatly over the course of a year, month, week, or day, traffic data needed to be collected during “typical” peak-hour conditions. The Coachella Valley is a seasonal tourist destination. Because of this, the traffic during the winter months is much different from the summer. Although temporal traffic highs and lows are typically avoided, it is important to design roadway facilities for the busier timeframe to accommodate the greater amount of traffic. It is recognized that during the months of January through March there is a peak seasonal volume of traffic to the Coachella Valley, therefore the data was collected during these months in 2010. Also, because of unpredictable spikes in daily traffic volumes due to the significant amounts of weekend travelers, data was collected during typical weekdays between Tuesday and Thursday.

The peak times when a roadway experiences the most demand are important to the calculation of the LOS and helps to understand which segments are not meeting the peak demands of traffic. Since traffic volume data was collected over 24-hour periods for each direction of travel per hour, the data was broken into the typical three peak periods: AM (7:00 a.m. to 9:00 a.m.), Mid-day (11:00 a.m. to 2:00 p.m.), and PM (4:00 p.m. to 6:00 p.m.). The peak hour for each direction within each of those periods was used in the analysis. This volume information was used to calculate the V/C ratio for both directions of each segment for all of the three periods. This is described in the “*Calculating V/C Ratios and LOS Ratings for Segments*” sections of this chapter.

Peak hour traffic turning movements for the study intersections were collected during all three peak periods and was used to calculate the ICU critical flow ratios and corresponding LOS. This is described below in “*Calculating ICU and LOS Ratings for Intersections*”.

Determining Lane Capacity for Segments

The first step in computing a segment’s capacity is to develop a potential capacity that each travel lane could expect to handle under the most favorable conditions. Many of the assumptions used in the previous TPPS were followed in this update to maintain continuity. The following describes each type of study segment and the assumed capacities used in calculating the V/C ratios.

Uncontrolled Segment

As with the previous study, one of the predominant factors in determining a lane’s capacity is the type of roadway control assigned to the segment. Uncontrolled segments are considered to be virtually free-flowing roadways during non-congested conditions, with no traffic control restrictions, except on intersecting side streets. The base capacity for uncontrolled arterials is assumed to be 1,800 vehicles per hour, per lane.

Signal-Controlled Segment

Due to the nature of traffic signals controlling and shifting the vehicular right-of-way to the side streets, signalized segments are considered to have less capacity than that of an uncontrolled segment’s. Assuming the signal’s cycle length is evenly split between both intersecting streets, the capacity equals 50% of an uncontrolled capacity, or 900 vehicles per hour, per lane.

Stop-Controlled Segment

Arterials with stop controlled intersections have a significantly reduced potential segment capacity, since all traffic is required to stop. As the Highway Capacity Manual (HCM) reports, the capacity of a four-way stop-controlled intersection with one approach lane in each direction varies depending on the directional split of traffic at the intersection. Assuming a 50/50 split, the intersection’s capacity is assumed to be 1,900 vehicles per hour, or 475 vehicles per approach. However, assuming a 70/30 split, the intersection’s capacity is reduced to 1,500 vehicles per hour, or 525 vehicles per approach on the major street. By averaging both 475 veh/hr and 525 veh/hr, the hourly capacity for a stop-controlled arterial is assumed to be 500 vehicles per hour, per lane.

Left Turn Capacity Reductions

Capacity can be reduced on a roadway due to several factors. As was assumed in this study, reductions in capacity can also be expected if a roadway has limited maneuverability for left turning vehicles. In order to determine how the segment capacity may be reduced, the type of median and the intersection control were used. Each control type has a unique traffic distribution associated with it and therefore depending on the control type, certain ones can create gaps in traffic that can lessen the extent that left turns are expected to impede segment traffic.

"Raised Medians"

Studies have shown that raised medians do measurably benefit the capacity of a roadway. Access from side streets limits left turning to and from the main segment, increasing capacity on the main segment. Also, the median acts to buffer the driver from oncoming traffic, therefore providing some level of comfort that is not present with the absence of raised medians.

Example 1:

Left Turn Reduction (Uncontrolled, Signalized, or Stop-Cont. Art. with "Raised" Medians) =
 (Capacity) x 0% = 0 veh/hr/median lane

"All Left Turns" or TWLTL"

Although the existence of left turn lanes eliminates most traffic flow conflicts from left turning vehicles, the lack of a median buffer creates some perceived friction. Consequently the capacity is assumed to be only 5% less when there are no raised medians present, regardless of the roadway's control type. **Example 2** illustrates this reduction.

Example 2:

Left Turn Reduction (Uncontrolled Arterial with "All Left Turns" or "TWLTL") =

$$1,800 \text{ veh/hr/lane} \times 5\% = 90 \text{ veh/hr/median lane}$$

Left Turn Reduction (Signalized Arterial with "All Left Turns" or "TWLTL") =

$$900 \text{ veh/hr/lane} \times 5\% = 45 \text{ veh/hr/median lane}$$

Left Turn Reduction (Stop-Cont. Art. w/ "All Left Turns", "TWTWL") =

$$500 \text{ veh/hr/lane} \times 5\% = 25 \text{ veh/hr/median lane}$$

“Double Yellow Only” or “Intersection Left Turns”

Uncontrolled arterials that do not provide for left turns along the length of the segment can significantly reduce the capacity of a free-flowing roadway. Uncontrolled traffic flow is generally randomly distributed and does not form traffic platoons and gaps in traffic. Therefore, if left turns are not accommodated at all intersections, major driveways, or by a designated two-way left turn lane (TWLTL), capacity of the lane adjacent to the median was reduced by 50%. **Example 3** shows this scenario.

Example 3:

Left Turn Reduction (Uncontrolled Arterial with “DY Only” or “Int Left Turns”) =

$$1,800 \text{ veh/hr/lane} \times 50\% = 900 \text{ veh/hr/median lane}$$

Signalized arterial capacity is also reduced without the presence of adequate left turn lanes. However, signals will produce gaps in the mainline traffic stream that will allow for left turns on occasion, thereby reducing the likelihood that traffic will be extensively impeded. Because of this slight benefit of the traffic signal gap effect, left turn reduction in capacity is assumed to be only 33% for the lane closest to the median, as shown in **Example 4**.

Example 4:

Left Turn Reduction (Signalized Arterial with “DY Only” or “Int Left Turns”) =

$$900 \text{ veh/hr/lane} \times 33\% = 300 \text{ veh/hr/median lane}$$

Typically, stop-sign controlled arterials will only stop at other arterials. Stop controls for these arterials are usually predicated on lower volumes. Because of this, left turns from these arterials are generally less difficult and do not further reduce traffic capacity further than 5% of its already lowered assumed value (see Example 2).

Potential Hourly Capacity

The main characteristic of a roadway that determines its capacity is the number of lanes available for traffic. Once the capacity of each lane was determined through the methods shown above, it was multiplied by the number of lanes to produce the segment's total potential directional capacities. The segment's applicable left turn reduction is then subtracted from its potential capacity to arrive at its total hourly capacity, shown in **Equations 4-1 and 4-2** and **Example 5** below. Refer to **Table 4-3** at the end of this chapter for the developed capacities for all study segments.

Eq. 4-1:

$$\text{Potential Capacity (veh/hr)} = \text{Lane Capacity (veh/hr/lane)} \times \text{Number of Lanes}$$

Eq. 4-2:

$$\text{Hourly Capacity (veh/hr)} = \text{Potential Capacity (veh/hr)} - \text{Left Turn Capacity Reduction (veh/hr)}$$

Example 5:

Potential Capacity (Uncontrolled Arterial with 2 NB, 2 SB lanes, “All Left Turns” or “TWLTL”) =

$$1,800 \text{ veh/hr/lane} \times 2 \text{ Lanes} = 3,600 \text{ veh/hr}$$

Hourly Capacity (Uncontrolled Arterial with 2 NB, 2 SB lanes, “All Left Turns” or “TWLTL”) =

$$3,600 \text{ veh/hr/lane} - 90 \text{ veh/hr} = 3,510 \text{ veh/hr}$$

Calculating V/C Ratios and LOS Ratings for Segments

As stated earlier, the V/C ratios are simply the directional traffic volume collected divided by the calculated hourly traffic capacity, respectively. **Equation 4-3** summarizes this:

Eq. 4-3:

$$\text{V/C Ratio} = \left(\frac{\text{Volume (veh/hr)}}{\text{Capacity (veh/hr)}} \right)$$

Since the peak hour segment volume is directional, the higher of the two directions for each peak period is carried through the analysis. The V/C ratios for each peak period are converted to the corresponding LOS ratings, from 0 to 5 (A to F) using **Table 4-1**. The LOS gives a snapshot of the daily peak-hour operations of each segment.

For this analysis, one LOS is necessary for each study segment, therefore the LOS rating for each segment's peak period are assigned weights, depending on their relative LOS value. The highest value is assigned the highest weight which is weighted by a factor off three. The subsequent second highest LOS value is weighted by two and the lowest value by one. Each LOS value is then weighted, summed and averaged by dividing by 6. The average ratings for each segment are then rounded to the next highest integer as a final LOS value. **Equations 4-4 and 4-5** show the formulas used and **Example 6** demonstrates this procedure. The study segment volumes and calculated V/C ratio values are listed in **Table 4-4**.

Eq. 4-4:

$$\begin{aligned} \text{Total Weighted Points} = & \\ & (\text{High Pk-Hr LOS Rating} \times 3) + (\text{Mid Pk-Hr LOS Rating} \times 2) \\ & + (\text{Low Pk-Hr LOS Rating} \times 1) \end{aligned}$$

Eq. 4-5:

$$\text{Average LOS Value} = \left(\frac{\text{Total Weighted Points}}{6} \right)$$

Example 6:

AM Peak Period

$$\text{V/C Ratio, NB} = (228 \text{ veh/hr}) / (475 \text{ veh/hr}) = \mathbf{0.48}$$

$$\text{V/C Ratio, SB} = (156 \text{ veh/hr}) / (475 \text{ veh/hr}) = 0.33$$

Midday Peak Period

$$\text{V/C Ratio, NB} = (356 \text{ veh/hr}) / (475 \text{ veh/hr}) = \mathbf{0.75}$$

$$\text{V/C Ratio, SB} = (226 \text{ veh/hr}) / (475 \text{ veh/hr}) = 0.48$$

PM Peak Period

$$\text{V/C Ratio, NB} = (504 \text{ veh/hr}) / (475 \text{ veh/hr}) = \mathbf{1.06}$$

$$\text{V/C Ratio, SB} = (290 \text{ veh/hr}) / (475 \text{ veh/hr}) = 0.61$$

Using Highest V/C ratio in bold above:

$$\text{AM V/C Ratio, NB} = 0.48 = \text{LOS "A"}^* = 0 \text{ pts}^*$$

$$\text{Midday V/C Ratio, NB} = 0.75 = \text{LOS "C"}^* = 2 \text{ pts}^*$$

$$\text{PM V/C Ratio, NB} = 1.06 = \text{LOS "F"}^* = 5 \text{ pts}^*$$

* Using Table 4-1

Total Weighted Points =

$$(5 \text{ pts.} \times 3) + (2 \text{ pts.} \times 2) + (0 \text{ pts.} \times 1) = 19 \text{ pts.}$$

$$\text{Average LOS Value} = \left(\frac{19 \text{ pts}}{6} \right) = 3.2 \text{ pts}$$

Rounded up to 4 pts. = LOS "E"

For the study segments, the Average LOS Value is equivalent to the LOS criteria score.

Calculating ICU and LOS Ratings for Intersections

The operation at intersections is different from how roadway segments may operate, therefore the LOS ratings were derived differently than arterial segments. The intensity of the conflicting traffic movements at an intersection tends to define how well it operates. For the intersections, the levels of service were calculated utilizing the Intersection Capacity Utilization (ICU) methodology. This method uses peak hour critical flow ratios for each lane to sum the amount of time required to serve all traffic movements. The ICU method is commonly used in planning documents and is designed to be compatible with Highway Capacity Manual (HCM) and other methods. The ICU analyses were performed in the Synchro software program which automates the calculations by inputting intersection characteristics and peak hour traffic volumes.

Assumptions used in the ICU are critical to the output that the Synchro software will produce. In an effort to maintain consistency with the previous TPPS update, the following assumptions for the intersections were coded into the Synchro software for this analysis:

- 1,800 veh/hr for through lanes (when green, or movement permitted)
- 1,600 veh/hr for left turn lanes (when green, or movement permitted)
- 6 seconds of lost time for the clearance interval
- Protected left turns
- Signal cycle length to be 100 seconds

Synchro then calculated the intersection capacity utilization for each of the peak hour periods, AM, Mid-day, and PM. As with the roadway segments, the ICU values were compared to LOS thresholds in **Table 4-1** to give a resulting LOS value. ICU Calculation sheets for all intersections can be found in **Appendix A**, at the end of this report.

LEVEL OF SERVICE SCORING

Results of the level of service criteria analysis are shown in **Table 4-5**. Table 4-5 includes a comparison of the results of this TPPS update LOS scoring to the previous update's scoring results. Roadways that do not exist are given the same rating as the highest, adjacent studied segment on that arterial. Interchanges are given a rating equal to the highest, adjacent, studied interchange

CHAPTER 5

ACCIDENT RATE

BACKGROUND

The accident rate scoring criteria includes scoring the road segments and intersections within the study based upon the relative rate of accidents. The traffic accident criteria ranks each individual road segment in the TPPS based on the overall accident rate following the procedural guidelines recommended by the *Transportation and Traffic Engineering Handbook (Second Edition)* published by the Institute of Transportation Engineers (ITE) and *Accident Data on California State Highways* publications from Caltrans. Accident rates are calculated using volumes, degree of severity, and segment lengths, except for study intersections, which do not require length as a variable in their rate calculations. The methodology used to establish the traffic accident criteria for roadway segments and intersections and the methodology to rank the results is described below in detail.

ACCIDENT RATE METHODOLOGY

The ITE and Caltrans accident rate guidelines recommend that when completing accident analysis that the frequency and severity of the accidents should be considered. The frequency is the number of accidents that occur over each study segment over the specified timeframe to quantify the degree of loss per accident. Additionally, the severity rates are interpreted to use the number of parties that resulted in injuries or fatalities in an incident, instead of qualifying each accident event as injury, fatality, or property-damage only. The severity rate is a combination of personal injury and fatal accidents that occur over the specified timeframe. The overall accident rate was then calculated using all of the data.

5 Year Trend For The Top 10 Counties of 2008 - Fatalities

Riverside County had the 3rd highest reduction in fatalities

ACCIDENT DATA

This scoring criterion for accident rates is based on accurate reporting and data collection of accidents within the study area. The primary source of accident data comes from the Statewide Integrated Traffic Records System (SWITRS), which is a centralized accident database maintained by the California Highway Patrol (CHP) that serves as a hub of local (city or county) and state police agency information. SWITRS includes information for accidents involving injuries, fatalities, and a large proportion of the “property damage only” motor vehicle traffic accidents reported in California. The SWITRS data used in this study compiles only accidents that are reported. As a result, there are always a large amount of PDO accidents that do occur but are not reported along the study segments and are not included in the SWITRS database or this study. The raw accident data is reduced into usable data and sorted into the proper studied segments. As an option, agencies were also able to provide alternative data if available, provided that the data provided was complete enough to calculate the necessary rates.

All accident reports are checked for completeness, coded, key punched and processed into a computer database. The computerized data is then available in the form of special reports for participating cities and counties and other State agencies. Due to the length of time required to process the accident reports, complete SWITRS information is only available up to the year 2008 at the time of this report. The most current three years of data, beginning January 1, 2006 and ending December 31, 2008, was requested from the CHP and was received as a large batch-file in raw form.

The raw data was imported into a spreadsheet and reduced by eliminating accidents that were not within the study segments. The accident data was then interpreted using identifiers such as primary and secondary streets, direction, distance, and highway post-mile, to help discern the location of each accident. If an accident occurred at an intersection that was shared by multiple segments, the event was applied to all shared segments. Accidents within 200 feet of a study intersection or study interchange (measured from its ramps) were applied to that particular intersection or interchange only. After all applicable accident events were assigned to study segments, the total number of accidents, personal injuries and fatalities, were calculated for each segment.

Table 5-2 summarizes each study segment’s accident data characteristics.

FREQUENCY OF ACCIDENTS

This information was translated into a frequency rate based upon the amount of traffic to which a segment was exposed. Since the study includes both roadway segments and intersections, different equations are necessary to calculate the accident rates.

The data utilized to calculate the accident frequency rates include:

- Roadway segment length (feet)
- Roadway segment average daily traffic (ADT)
- Intersection daily entering volume
- Total number of accidents for segments and intersections

Interchanges and bridges were treated as segments. Interchange length is estimated based upon the distance between ramps and 200 feet beyond and bridge length is from the apparent beginning to end of the bridge's span.

Roadway Segment Accident Rates

For segments, the common unit used in this practice to report frequency rate is in "accidents per million vehicle miles." Because the accidents frequency must account for different roadway segment lengths as well as time periods, the analysis must "normalize" the data which is converting the accident frequencies to a common timeframe. To do this, the total number of vehicle miles traveled in three years was calculated using the average daily traffic (ADT) and length of each roadway segment. If no ADT was available, the ADT from an adjacent segment was assumed. Accident rates for roadway segments are normally expressed in terms of million vehicle miles (MVM). The Equations 5-1 and 5-2 below illustrate the formulas used in the analysis for roadway segments.

Eq. 5-1:

Total Veh-Mi Traveled in 3 Yrs =

$(\text{Segment ADT} \times 3 \text{ yrs} \times 365 \text{ days}) \times (\text{Segment Length} / 5280 \text{ ft})$

Eq. 5-2:

Segment Accident Frequency Rate per MVM =

$$\left(\frac{\# \text{ of Accidents} \times 1,000,000}{\text{Total Veh - Mi Traveled in 3 Yrs}} \right)$$

Intersection Accident Rates

Similarly, for intersections, the basis to calculate accident frequency takes the number of accidents over the total number of vehicles that entered the intersection. This is normally expressed as million entering vehicles (MEV). The total number of daily entering vehicles was estimated using a common traffic engineering principle of multiplying the average peak hour volume by ten. Accidents within 200 feet of a study intersection were applied to that particular intersection only. Equations 5-3 and 5-4 below illustrate the formulas used in the analysis for the intersections.

Eq. 5-3:

Total Entering Vehicles in 3 Yrs = (Average Peak Hour Volume x 10 x 3 yrs x 365 days)

Eq. 5-4:

Intersection Accident Frequency Rate per MEV =

$$\left(\frac{\text{\# of Accidents} \times 1,000,000}{\text{Total Entering Vehicles in 3 Yrs}} \right)$$

SEVERITY RATE

The accident frequency is helpful in determining the relative quantity of accidents that the study segments experience. A secondary component, severity rate, applies intensities to these frequencies and further qualifies the accident rates for each segment. The SWTRS data reports accident severity by quantifying the number of injuries and fatalities that resulted from each incident. Although the database does list "severe injuries", versus "other visible injuries" and "complaints of pain," these descriptors are somewhat subjective. There is no mention of any citable difference in severity of PDO or fatality type accidents. Similar to accident frequency, segment rates are figured using million-vehicle-miles (MVM) and intersection rates use millions-of-vehicles-entering (MEV) units, instead.

The data utilized to calculate the accident severity rates include:

Roadway segment length (feet)

Roadway segment average daily traffic (ADT)

Intersection daily entering volume

Total number of injuries and fatalities for segments and intersections

Severity rates are based upon the relative intensities of accident types. A fatal accident is considered more severe than one involving solely personal injury. Therefore, a factor is used to weight each type of accident accordingly. These weighted factors provide a relationship of importance associated with the personal injury or fatality-type accidents. For purposes of this analysis, a fatal accident was assigned twice the weight of a personal injury accident. Severity rates are determined for the road segments and intersections using Equations 5-5 and 5-6 below:

Eq. 5-5:

Segment Severity Rate (MVM) =

$$1 + \left(\frac{(1 \times \text{\# of injuries}) + (2 \times \text{\# of fatalities}) \times 1,000,000}{\text{Total Veh - Mi Traveled in 3 Yrs}} \right)$$

Eq. 5-6:

Intersection Severity Rate (MEV) =

$$1 + \left(\frac{(1 \times \text{\# of injuries}) + (2 \times \text{\# of fatalities}) \times 1,000,000}{\text{Total Entering Vehicles in 3 Yrs}} \right)$$

It should be noted that only one accident might be counted per event despite the fact that it may involve several parties or vehicles. However, one event may have multiple injuries, fatalities, or a combination of these. The baseline severity rate is considered 1.00, which assumes all accidents were property-damage only (PDO) accidents only, without injuries or fatalities.

OVERALL ACCIDENT RATE

The overall accident rate can be generally defined as the significant relationship that exists between accident frequency and severity for each project segment. The overall accident rate is expressed in Equation 5-7:

Eq. 5-7:

$$\text{Overall Accident Rate} = (\text{Frequency Rate} \times \text{Severity Rate})$$

If a segment or intersection had no reported accidents, the Frequency Rate would equal zero as would the Overall Accident Rate. If a segment or intersection did experience accidents, but had no reported injuries or fatalities, the Severity Rate would equal 1.00 and the Accident Frequency Rate would then equal the Overall Accident Rate.

Segments which are missing links and other new facilities will generally have accident rates of zero, and a score of zero points. There are some segments that are designated as a new road, bridge, or interchange that may have some partially constructed section with reported accidents and a measured ADT. These segments will generally still have a lower rate, as it is averaged over the total length of the segment, constructed or not.

Refer to **Table 5-3** for the accident frequency rate, severity rate, and overall accident rate for each study segment and intersection.

Statewide fatalities per 100 million VMT

ACCIDENT RATE SCORING

Scoring of the roadway segments and intersections based on the accident criteria will attribute higher scores to segments that have been shown to have higher accidents rates. The traffic accident ranking uses the same method as the 2005 TPPS update. The segments are assigned point values from zero to five, ranking them from lowest to highest overall accident rates. Once overall accident rates were calculated for each segment, scores were given using pre-determined value ranges, shown in **Table 5-1**.

Table 5-1 Accident Rate Scoring Criteria

Points	Overall Accident Rate
0	0.00
1	0.01 - 0.90
2	0.91 - 3.90
3	3.91 - 6.90
4	6.91 - 9.90
5	9.91 +

CHAPTER 6

BONUS POINT CRITERIA

BACKGROUND

Segments within the TPPS study can also qualify for extra “bonus” points based upon characteristics chosen by the CVAG and the TTAS board members, which add to the total score each segment receives.

BONUS POINT CRITERIA

This update includes bonuses for those segments that meet certain criteria. A total of three bonus points can be earned in this study. One point is awarded to each segment for each of the following criteria that it meets:

- Construction cost of the segment is less than \$1,000,000
- Project meets “project readiness criteria” and is nearly ready for construction.
- Segment crosses a Whitewater River tributary
- Backbone Project

These criteria and respective possible bonus point values are listed in the following **Table 6-1**.

Table 6-1 | Bonus Point Criterion

Points	Bonus Point Criterion
1	Construction Cost for Buildable Project is Less Than \$1,000,000
1/2 to 1	Project Readiness: If R/W Available, Env. Document Approved, Agency Funds Reserved, Plans or Specs Complete
1/2	Segment is a Whitewater River (or Major Tributary) Crossing
1/2	Segment meets criteria as a Backbone Level Project

Whitewater Bridge

Construction Cost < \$1,000,000

Construction costs for each segment are determined in the Regional Arterial Cost Estimate (RACE) document that supplements this study. For each segment that is planned to cost less than \$1,000,000 to construct, not including right-of-way and other factors listed in the RACE document.

Project Readiness

If a segment is ready for construction pending additional funding, it could qualify for a project readiness bonus point. This criterion requires the project be designed with specifications complete, environmental documents ready, all right-of-way acquired, and matching local funds in order. If one or two of these conditions are met, the segment will receive one-half of a bonus point. If three or four of the conditions are met, the segment will receive a full bonus point. Each agency was responsible for reporting the project readiness for each project under their jurisdiction.

Whitewater Tributary

Many streets are designed to let minor rain events flow over the roadway at low-water crossings instead of more expensive bridge structures. Due to the nature of the desert climate, rainfall is not generally an issue regarding mobility. However, during heavy storms runoff from rain events can collect quickly from the surrounding mountains and create areas of isolation, leaving many routes unusable until the rains subside. The Whitewater River is the primary water basin in the valley and therefore carries the highest priority for upgrading the streets and bridges over it. If a segment crosses the Whitewater River or a blue-line stream that appears on a USGS Quadrangle map that serves as a tributary to the Whitewater River, the segment is given one-half of a bonus point.

Backbone Projects

Backbone projects are considered generally more visible because of their overall importance to the CVAG arterial network. Based upon a definition by the CVAG TPPS committee, a Backbone project is defined as a segment that is part of Highway 111, crosses the Whitewater River, or serves as an interchange to I-10 or SR-86S. Backbone projects will be awarded one-half of a bonus point because of this priority.

SCORING

Table 6-2 evaluates each segment's bonus point characteristics, while **Table 6-3** tallies the bonus points awarded.

CHAPTER 7

ROAD SEGMENT SCORING

BACKGROUND

The TPPS study serves as an unbiased, methodological way to provide CVAG direction in determining funding for regional arterials by prioritizing the eligible study segments. This chapter summarizes the scoring results of the previous TPPS chapters.

UNIFORM ROAD SEGMENTS TOTALS

A segment's overall score is a sum of the points it earns from the four criteria set forth in the earlier chapters of this study and three potential bonus points. The maximum score any one segment may receive is 5 points for each of the four main criteria and 3 additional bonus points, totaling 23 points. **Table 7-1** reports the total scores for each uniform road segment and compares it to its score from the previous study.

BUILDABLE PROJECTS

After all segments have been analyzed using criteria set forth by CVAG and the TTAS, they are scored and ranked. The segments can then be merged or divided into logical and feasibly constructible buildable projects. Buildable projects were defined and organized in the RACE Chapter 1.

Scoring Buildable Projects

The score for a buildable project is simply the average of the score for each segment that is part of its defined limits. All bonuses, including the construction cost bonus are maintained for a segment's score, even if it becomes part of a buildable project that would not have met the criteria after combining segments.

Agencies have input into defining buildable project limits and may choose to combine segments in order to achieve what is perceived

to be a more desirable scoring outcome. Because scores for a buildable project are averages of included segments, it makes this procedure more suitable for combining the higher scoring study segments. An example of this may be to include an intersection with an adjacent segment that has scored well to have a high-ranking average score for both segments. This is structured to keep the highest priority segments together, without artificially raising lower scoring segments to achieve a higher rank. **Table 7-2** lists the scores for each buildable project defined in the RACE Chapter 1 study using the scoring results in this chapter.

TOTAL TPPS RANKINGS

The rankings will only serve as a tool for CVAG to assisting in prioritizing project funding for eligible transportation infrastructure projects. Many factors must be considered when allotting funds for buildable projects and those projects that score highly may not necessarily be considered funding priorities due to other factors, such as development or project size. **Table 7-3** shows the buildable project rankings based on their total scores.
